

MPEI — crawl simulation

Paulo J S G Ferreira

3rd December 2014

Consider the following set of linked pages:

Handwritten matrix H:

	1	2	3	4
1	0.8	0.2	0	0
2	0	0.9	0.1	0
3	0.3	0.2	0.4	0.1
4	0	0	0	1

- Write the matrix H (transition probability matrix: H_{ij} is the probability of going from page i to page j , in one step).
- Find the probability of reaching page j starting from page i , in 1, 2, 10 and 100 steps.
- Find Q and the fundamental matrix $F = (I - Q)^{-1}$.
- What is the average number of steps required to reach state 4 starting from page 1? And if one starts in page 2? What about page 3? *1-4 → 5 steps*
2-4 → 10 steps
3-4 → ?
- Confirm the values by simulation (average several runs). The **octave** code on the next page may help.
- Modify the matrix H to increase the absorption time.

$futuro = nextState(H, atual)$ → determina o ponto seguinte do trajeto, segundo o ponto atual

an example state transition matrix (page 3 is absorbing)

```
H = [0.9  0.1  0   ;
      0.5  0.4  0.1 ;
      0    0    1   ];
```

Cada crawler vai ter que possuir uma função deste tipo (discrete-rnd) que lhe atribua uma posição segundo certa probabilidade

the fundamental matrix

```
Q = H(1:2,1:2);
```

```
F = inv(eye(2)-Q) → F =  $\begin{bmatrix} 0.0 & 1.0 \\ 5.0 & 1.0 \end{bmatrix}$ 
```

começando em 1, em média 5 vezes posso par 1 e 2 50% e 50% respectivamente

given a transition matrix and the current state,

this function returns the next state

```
function state = nextState(H, currentState)
```

find the probabilities of reaching all pages starting at the current one

```
probVector = H(currentState,:);
```

n is the number of pages, that is, H is n x n

```
n = length(probVector);
```

pick the next page randomly according to those probabilities

```
state = discrete_rnd(1:n, probVector, 1);
```

1 → nº de n's que vai retornar

```
endfunction
```

→ retorna valores numéricos e a prob. de o crawler estar em [1 2 3] [0.5 0.4 0.1]

random walk on the graph according to state transition matrix H

first = initial state, last = terminal or absorbing state

```
function state = crawl(H, first, last)
```

the sequence of states will be saved in the vector "state"

initially, the vector contains only the initial state

```
state = [first];
```

keep moving from page to page until page "last" is reached

```
while (1)
```

```
    state(end+1) = nextState(H, state(end));
```

```
    if (state(end) == last) break; endif
```

```
endwhile
```

```
endfunction
```

how to use crawl()

```
state = crawl(H, 1, 3);
```

→ podemos fazer um ^{ciclo} e contar as vezes que passo por certo estado, antes de ir para o estado absorvente

1º Trial

$$x = \text{rand}(1, 100) < 0.5$$

$$\text{sum}(x)$$

$$\text{ans} = 55$$

2º Trial

$$x = \text{rand}(1, 100) < 0.5$$

$$\text{sum}(x)$$

$$\text{ans} = 44$$

3º Trial

$$x = \text{rand}(1, 1000000) < 0.5$$

$$\text{ans} = 49975$$

6

$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$
x	x	0	0
x	0	x	0
x	0	0	x
0	x	0	x
0	0	x	x
0	0	x	0

Trobalhas a realizar

2.1 ~~total~~ total = 0;

for k = 1 : 100

ml = sum(rand(1, 100) < 0.5);

maxml = max(ml, maxml);

total = total + ml;

end

total / 100

ans = ~~8334~~ 500.15

maxml = 834

minml = 464

Para milereiras com contagem de 64:

...

for i = 1 : 1000

ml = sum(rand(1, 1000) < 1/64);

...

ans = 156.43

maxml = 26

minml = 3
